

# Introduction to Machine Learning

## Classification

## Linear Classifiers

### Learning goals

- Linear classifier
- Linear decision boundaries
- Linear separability

# LINEAR CLASSIFIERS

Important subclass of classification models.

Definition: If discriminant(s)  $f_k(\mathbf{x})$  can be written as affine linear function(s) (possibly through a rank-preserving, monotone transformation  $g$ ):

$$g(f_k(\mathbf{x})) = \mathbf{w}_k^\top \mathbf{x} + b_k,$$

we will call the classifier **linear**.

- $\mathbf{w}_k$  and  $b_k$  do not necessarily refer to parameters  $\theta_k$ , although they often coincide; discriminant simply must be writable in an affine-linear way
- reasons for the transformation is that we only care about the position of the decision boundary

# LINEAR DECISION BOUNDARIES

We can also easily show that the decision boundary between classes  $i$  and  $j$  is a hyperplane. For every  $\mathbf{x}$  where there is a tie in scores:

$$\begin{aligned}f_i(\mathbf{x}) &= f_j(\mathbf{x}) \\g(f_i(\mathbf{x})) &= g(f_j(\mathbf{x})) \\ \mathbf{w}_i^\top \mathbf{x} + b_i &= \mathbf{w}_j^\top \mathbf{x} + b_j \\ (\mathbf{w}_i - \mathbf{w}_j)^\top \mathbf{x} + (b_i - b_j) &= 0\end{aligned}$$

This represents a **hyperplane** separating two classes:

# EXAMPLE: 2 CLASSES WITH CENTROIDS

- Model binary problem with centroid  $\mu_k$  per class as "parameters"
- Don't really care how the centroids are estimated;  
could use class means, but the following doesn't depend on it
- Classify point  $\mathbf{x}$  by assigning it to class  $k$  of nearest centroid

## EXAMPLE: 2 CLASSES WITH CENTROIDS

Let's calculate the decision boundary:

$$d_1 = \|\mathbf{x} - \mu_1\|^2 = \mathbf{x}^\top \mathbf{x} - 2\mathbf{x}^\top \mu_1 + \mu_1^\top \mu_1 = \mathbf{x}^\top \mathbf{x} - 2\mathbf{x}^\top \mu_2 + \mu_2^\top \mu_2 = \|\mathbf{x} - \mu_2\|^2 = d_2$$

Where  $d$  is measured using Euclidean distance. This implies:

$$-2\mathbf{x}^\top \mu_1 + \mu_1^\top \mu_1 = -2\mathbf{x}^\top \mu_2 + \mu_2^\top \mu_2$$

Which simplifies to:

$$2\mathbf{x}^\top (\mu_2 - \mu_1) = \mu_2^\top \mu_2 - \mu_1^\top \mu_1$$

Thus, it's a linear classifier!

# LINEAR SEPARABILITY

If there exists a linear classifier that perfectly separates the classes of some dataset, the data are called **linearly separable**.

# FEATURE TRANSFORMATIONS

Note that linear classifiers can represent **non-linear** decision boundaries in the original input space if we use derived features like higher order interactions, polynomial features, etc.

Here we used absolute values to find suitable derived features.
