

# Introduction to Machine Learning

## ML-Basics Learner

### Learning goals

- Know formal definition of learner
- Understand that a learner receives training data and outputs the best model from  $\mathcal{H}$

## SUPERVISED LEARNING EXAMPLE

- Imagine we want to investigate how working conditions affect productivity of employees
- It is a **regression** task since the target *productivity* is continuous
- We collect data about worked minutes per week (*productivity*), how many people work in the same office as the employee in question, and the employee's salary

Features $x$		Target $y$
People in Office (Feature 1) $x_1$	Salary (Feature 2) $x_2$	Worked Minutes Week (Target Variable)
4	4300 €	2220
12	2700 €	1800
5	3100 €	1920

Diagram illustrating the data structure for a regression problem:

- The data is organized into a table with 3 rows and 3 columns.
- The first two columns represent the features ( $x$ ), and the third column represents the target variable ( $y$ ).
- The features are:
  - Feature 1 ( $x_1$ ): People in Office
  - Feature 2 ( $x_2$ ): Salary
- The target variable is: Target Variable ( $y$ ): Worked Minutes Week.
- The data points are:
  - Row 1:  $x_1 = 4$ ,  $x_2 = 4300$  €,  $y = 2220$
  - Row 2:  $x_1 = 12$ ,  $x_2 = 2700$  €,  $y = 1800$
  - Row 3:  $x_1 = 5$ ,  $x_2 = 3100$  €,  $y = 1920$
- The number of samples is  $n = 3$ .
- The number of features is  $p = 2$ .
- The input features are collectively denoted as  $x^{(2)}$ .
- The target variable is denoted as  $y^{(3)}$ .

# SUPERVISED LEARNING EXAMPLE

How could we construct a model from these data?

We could investigate the data manually and come up with a simple, hand-crafted rule such as:

- The baseline productivity of an employee with salary 3000 and 7 people in the office is 1850 minutes
- A decrease of 1 person in the office increases productivity by 30
- An increase of the salary by 100 increases productivity by 10

⇒ Obviously, this is neither feasible nor leads to a good model.

# IDEA OF SUPERVISED LEARNING

- **Goal:** Identify the functional relationship that maps features to target
- **Supervised** learning means we use *labeled* data to learn model  $f$
- Later, we use model  $f$  to predict  $y$  for new *unlabeled* data

# LEARNER DEFINITION

- Algorithm for finding  $f$  is called **learner** / **learning algorithm** / **inducer**
- The learner is our means of picking the best element from the hypothesis space  $\mathcal{H}$  for given training data
- Formally it maps training data  $\mathcal{D} \in \mathbb{D}$  (plus a vector of **hyperparameter** control settings  $\lambda \in \Lambda$ ) to a model:

$$\mathcal{I} : \mathbb{D} \times \Lambda \rightarrow \mathcal{H}$$

- Practically, we often construct a mapping  $\mathcal{I} : \mathbb{D} \times \Lambda \rightarrow \Theta$

# LEARNER DEFINITION

In pseudo-code:

- Learner gets a hypothesis space of parametrized functions  $\mathcal{H}$
- User passes data set  $\mathcal{D}_{\text{train}}$  and control settings  $\lambda$
- Learner sets parameters such that model fits data best
- Optimal parameters  $\hat{\theta}$  or function  $\hat{f}$  is returned for later usage
