

Introduction to Machine Learning

Evaluation ROC Basics

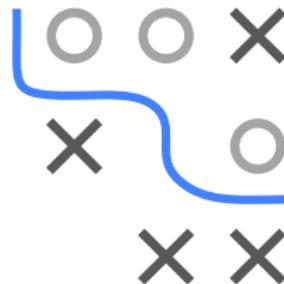

Learning goals

- Understand why accuracy is not an optimal performance measure for imbalanced labels
- Understand the different measures computable from a confusion matrix
- Be aware that each of these measures has a variety of names

		True Class y			
		+	-		
Pred.	+	TP	FP	PPV =	$\frac{TP}{TP+FP}$
\hat{y}	-	FN	TN	NPV =	$\frac{TN}{FN+TN}$
TPR = $\frac{TP}{TP+FN}$		TNR = $\frac{TN}{FP+TN}$		Accuracy = $\frac{TP+TN}{TOTAL}$	

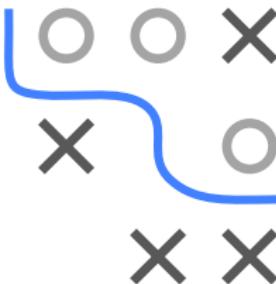

CLASS IMBALANCE

- Assume a binary classifier diagnoses a serious medical condition.
- Label distribution is often **imbalanced**, i.e, not many people have the disease.
- Evaluating on mce is often inappropriate for scenarios with imbalanced labels:
 - Assume that only 0.5 % have the disease.
 - Always predicting “no disease” has an mce of 0.5 %, corresponding to very high accuracy.
 - This sends all sick patients home → bad system
- This problem is known as the **accuracy paradox**.

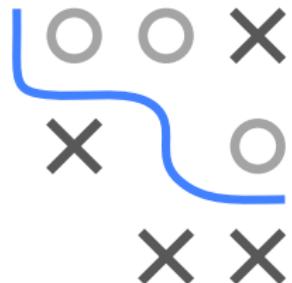

IMBALANCED COSTS

- Another point of view is **imbalanced costs**.
- In our example, classifying a sick patient as healthy should incur a much higher cost than classifying a healthy patient as sick.
- The costs depend a lot on what happens next: we can well assume that our system is some type of screening filter, and often the next step after labeling someone as sick might be a more invasive, expensive, but also more reliable test for the disease.
- Erroneously subjecting someone to this step is undesirable (psychological, economic, medical expense), but sending someone home to get worse or die seems much more so.
- Such situations not only arise under label imbalance, but also when costs differ (even though classes might be balanced).
- We could see this as imbalanced costs of misclassification, rather than imbalanced labels; both situations are tightly connected.

ROC ANALYSIS

- **ROC analysis** is a subfield of ML which studies the evaluation of binary prediction systems.
- ROC stands for “receiver operating characteristics” and was initially developed by electrical engineers and radar engineers during World War II for detecting enemy objects in battlefields – still has the funny name.

LABELS: ROC METRICS

From the confusion matrix (binary case), we can calculate "ROC" metrics.

		True Class y		
		+	-	
Pred.	+	TP	FP	$\rho_{PPV} = \frac{TP}{TP+FP}$
\hat{y}	-	FN	TN	$\rho_{NPV} = \frac{TN}{FN+TN}$
		$\rho_{TPR} = \frac{TP}{TP+FN}$	$\rho_{TNR} = \frac{TN}{FP+TN}$	$\rho_{ACC} = \frac{TP+TN}{TOTAL}$

- True positive rate ρ_{TPR} : how many of the true 1s did we predict as 1?
- True Negative rate ρ_{TNR} : how many of the true 0s did we predict as 0?
- Positive predictive value ρ_{PPV} : if we predict 1, how likely is it a true 1?
- Negative predictive value ρ_{NPV} : if we predict 0, how likely is it a true 0?
- Accuracy ρ_{ACC} : how many instances did we predict correctly?

LABELS: ROC METRICS

Example:

		Actual Class y		
		Positive	Negative	
\hat{y} Pred.	Positive	True Positive (TP) = 20	False Positive (FP) = 180	Positive predictive value $= TP / (TP + FP)$ $= 20 / (20 + 180)$ $= 10\%$
	Negative	False Negative (FN) = 10	True Negative (TN) = 1820	Negative predictive value $= TN / (FN + TN)$ $= 1820 / (10 + 1820)$ $\approx 99.5\%$
		True Positive Rate $= TP / (TP + FN)$ $= 20 / (20 + 10)$ $\approx 67\%$	True Negative Rate $= TN / (FP + TN)$ $= 1820 / (180 + 1820)$ $= 91\%$

MORE METRICS AND ALTERNATIVE TERMINOLOGY

Unfortunately, for many concepts in ROC, 2-3 different terms exist.

		True condition			
		Total population	Condition positive	Condition negative	Prevalence $= \frac{\sum \text{Condition positive}}{\sum \text{Total population}}$
Predicted condition	Predicted condition positive	True positive, Power	False positive, Type I error	Positive predictive value (PPV), Precision $= \frac{\sum \text{True positive}}{\sum \text{Predicted condition positive}}$	Accuracy (ACC) = $\frac{\sum \text{True positive} + \sum \text{True negative}}{\sum \text{Total population}}$
	Predicted condition negative	False negative, Type II error	True negative	False omission rate (FOR) = $\frac{\sum \text{False negative}}{\sum \text{Predicted condition negative}}$	Negative predictive value (NPV) $= \frac{\sum \text{True negative}}{\sum \text{Predicted condition negative}}$
	True positive rate (TPR), Recall, Sensitivity, probability of detection $= \frac{\sum \text{True positive}}{\sum \text{Condition positive}}$	False positive rate (FPR), Fall-out, probability of false alarm $= \frac{\sum \text{False positive}}{\sum \text{Condition negative}}$	Positive likelihood ratio (LR+) $= \frac{\text{TPR}}{\text{FPR}}$	Diagnostic odds ratio (DOR) $= \frac{\text{LR+}}{\text{LR-}}$	$F_1 \text{ score} = \frac{1}{\frac{1}{\text{Recall}} + \frac{1}{\text{Precision}}} \cdot 2$
	False negative rate (FNR), Miss rate $= \frac{\sum \text{False negative}}{\sum \text{Condition positive}}$	Specificity (SPC), Selectivity, True negative rate (TNR) $= \frac{\sum \text{True negative}}{\sum \text{Condition negative}}$

LABELS: F_1 MEASURE

- It is difficult to achieve high **positive predictive value** and high **true positive rate** simultaneously.
- A classifier predicting more positive will be more sensitive (higher ρ_{TPR}), but it will also tend to give more *false* positives (lower ρ_{TNR} , lower ρ_{PPV}).
- A classifier that predicts more negatives will be more precise (higher ρ_{PPV}), but it will also produce more *false* negatives (lower ρ_{TPR}).

The F_1 **score** balances two conflicting goals:

- ➊ Maximizing positive predictive value
- ➋ Maximizing true positive rate

ρ_{F_1} is the harmonic mean of ρ_{PPV} and ρ_{TPR} :

$$\rho_{F_1} = 2 \cdot \frac{\rho_{PPV} \cdot \rho_{TPR}}{\rho_{PPV} + \rho_{TPR}}$$

Note that this measure still does not account for the number of true negatives.

WHICH METRIC TO USE?

- As we have seen, there is a plethora of methods.
→ This leaves practitioners with the question of which to use.
- Consider a small benchmark study.
 - We let k -NN, logistic regression, a classification tree, and a random forest compete on classifying the credit risk data.
 - The data consist of 1000 observations of borrowers' financial situation and their creditworthiness (good/bad) as target.
 - Predicted probabilities are thresholded at 0.5 for the positive class.
 - Depending on the metric we use, learners are ranked differently according to performance (value of respective performance measure in parentheses):

metric	k-NN	logistic regression	random forest	CART
TPR	2 (0.8777)	3 (0.8647)	1 (0.9257)	4 (0.8357)
TNR	4 (0.3764)	2 (0.4797)	3 (0.4072)	1 (0.4911)
PPV	4 (0.7665)	1 (0.7947)	3 (0.7842)	2 (0.7925)
F1	3 (0.8179)	2 (0.8279)	1 (0.8488)	4 (0.8130)
AUC	4 (0.7092)	2 (0.7731)	1 (0.7902)	3 (0.7293)
ACC	4 (0.7270)	2 (0.7490)	1 (0.7700)	3 (0.7320)
